

Green Policies and Transition Risk Propagation in Production Networks

By Pablo Aguilar, Beatriz González and Samuel Hurtado (Banco de España)

Keywords: climate change, green policies, carbon tax, input-output matrix.

JEL codes: Q48, H30.

We present a general equilibrium sectoral model designed to produce macroeconomic scenarios that incorporate transition risks associated with green policies. The model is calibrated to the Spanish economy, and it can simulate the impact of shocks to the price and coverage of greenhouse gas emission allowances, with particular attention to sectoral asymmetries arising from (i) the energy intensity of each industry, (ii) the source of that energy, and (iii) the interdependencies with other industries. We show that for an increase in the price of emission allowances similar to that observed in recent years (from approximately €25 per tonne of CO₂ in 2019 to almost €100 per tonne in 2022) the model predicts a cumulative decline in Spanish GDP after three years of 0.37%. The loss in value added is heterogeneous across industries, ranging from 4% in the most severely affected industries to virtually no impact in the least affected industries.

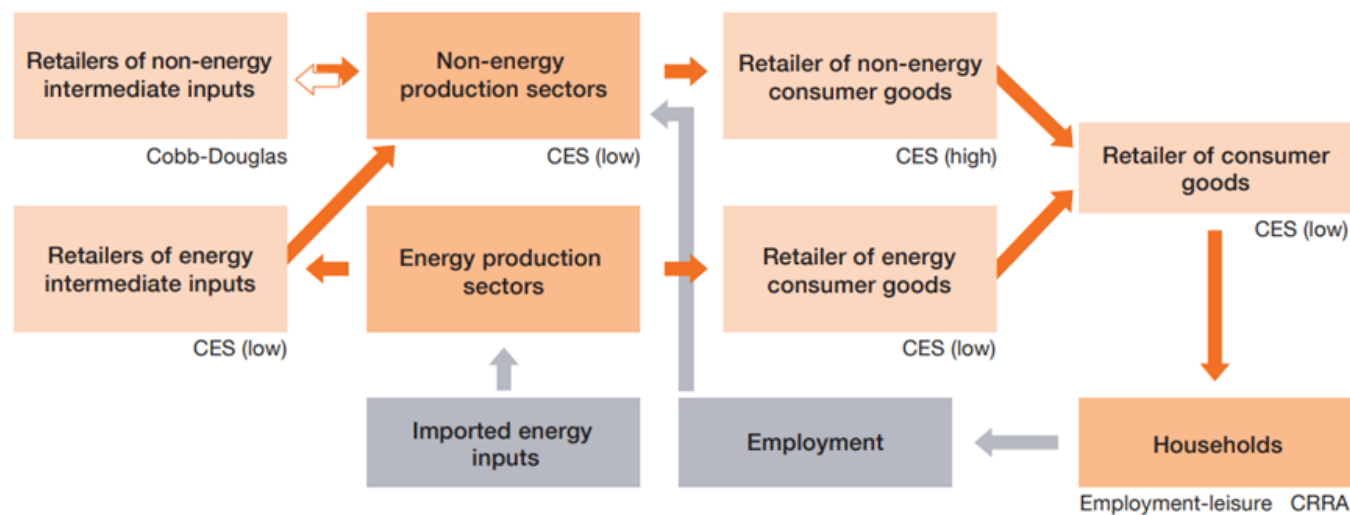

Description

Cross-sector differences in greenhouse gas (GHG) emission volume and intensity suggest that the green transition poses a highly uneven challenge for the different industries. An individual sector's exposure to the transition risks of climate change depends not only on its direct GHG emissions but also on the links with other sectors. In this note we propose a framework to account for this and quantify at a more granular level the transitional impact of green policies.

We develop a general equilibrium sectoral model à la Baqaee-Fahri to assess the implications of industries' asymmetrical exposure to the green transition process. The CATS¹ model is calibrated to the Spanish economy, and it can be used to generate short- and medium-term scenarios related to the transitions risks or policies taken to mitigate climate change. We use this model to assess the degree of exposure of different productive sectors in the event of an increase in the price of emission allowances or an extension of EU-ETS coverage.

The model has a highly granular structure, with 51 non-energy sectors and two energy sectors (fuel and electricity), and includes the cross-sectoral relationships contained in the input-output matrix. Figure 1 shows the different relationships in this economy: There is a final good that is produced combining the energy and non-energy final goods under a CES technology with low elasticity of substitution. Each of these two goods comes from a different retailer. The energy retailer aggregates the two energy inputs using a CES technology with low elasticity from the energy producers into a homogenous good. Likewise, the non-energy retailer aggregates the non-energy goods under a CES technology, with high elasticity of substitution in this case, coming from the 51 non-energy producer sectors. The production in this sector combines energy, labor and intermediate-inputs from the rest of the non-energy sectors under a CES function with low elasticity. The energy producer imports basic energy inputs from the rest of the world and sells to the non-energy and energy retailer. Finally, households consume the final good and work in the 51 non-energy sectors.

Figure 1: Summary representation of the model structure

¹ This paper was previously circulated under "Carbon Tax Sectoral Model" as published in <https://www.bde.es/f/webbde/SES/Secciones/Publicaciones/PublicacionesSeriasadas/DocumentosOcasionalas/22/Files/do2218e.pdf>. We maintain the short-name of CATS for its simplicity.

With this model we can identify the general equilibrium effects stemming from changes in the relative prices of the different economic sectors' products in response to different shocks, together with the magnitude of the potential substitution processes between different intermediate inputs and consumer goods in the economy. The characterization of the model is designed to be capable of capturing the different shares of energy in the production functions of the various industries, their emissions intensities, and the interrelations between them. The model calibration for Spain replicates the share of each sector in household consumption, the share of energy in the inputs of the various non-energy sectors, and the relative size of the various industries in terms of emissions and output.

Results

Figure 2 shows the impact of an increase in the price of emission allowances or an extension of EU-ETS coverage. In particular, in the event of an increase in the price of emission allowances similar to that observed in recent years (from approximately €25 per tonne of CO₂ in 2019 to almost €100 per tonne in early February 2022), the model predicts a cumulative decline of 0.6% in Spanish GDP after three years. If an extension of ETS coverage to include all productive sectors' emissions is added, the model predicts a fall of 1.3% in GDP after three years.²

Source: See Aguilar et al (2022).

a. Increase in price of CO₂ emissions, from €25 to €100 per tonne

b. Increase in price of CO₂ emissions, from €25 to €100 per tonne, and extension of coverage of EU-ETS to include all the emissions from all the productive sectors

²In any event, the scale of these aggregate impacts must be interpreted with the utmost caution. In particular, the model does not include certain aspects that could be critical for a quantitative determination of the implications of the green transition for the economy overall; for instance, the possibility of a non-linear acceleration in technological change or in the implementation of short-term energy efficiency measures in response to large shocks. Also, as with other models, the results of the CATS model are sensitive to certain assumptions and to the calibration of key parameters, such as the different economic sectors' capacity to substitute their inputs, and how the tax revenue stemming from the ETS is used.

The CATS model is particularly useful for a qualitative assessment of the potential sectoral asymmetries resulting from these policies. As shown in Figure 2, an increase in the price of ETS emissions reduces activity in non-energy sectors such as building materials and other non-metal mineral products, aviation, paper and chemical products. The impact is not necessarily higher in those generating larger emissions, but those that were covered by the ETS, or those trading heavily with sectors that are directly affected. This is the case, for example, of printing and recorded media, that buys a lot of inputs from paper manufacturers, and of repair and installation of machinery and equipment, that sells a lot of their products and services to various chemical and metal manufacturing sectors. On the other hand, sectors such as agriculture and fishing, that have relatively high emissions intensity, are not particularly affected by this shock, since their regulatory ETS coverage is low. On the other hand, in the simulation where ETS coverage is also extended, agriculture and fishing is one of the sectors most affected, together with transport sectors. As in the first simulation, some industries are indirectly hit through their commercial relations with other highly-affected sectors (warehousing and support for transportation, repair and installation of machinery and equipment, water collection and supply). In both scenarios there would be a significant reduction in energy use, which would be most acute in the case of fuels: the model predicts that higher emission prices and ETS coverage would accelerate the electrification of the economy.

As a conclusion, the heterogeneous impact of green policies may pose potential risks for financial stability and evidences the importance of the right diversification for banks to diminish their exposure to transition risks. We propose a framework to account for these effects that can be useful for building stress testing scenarios. ■

About the authors

Pablo Aguilar is Senior economist in the Macroeconomic Modelling unit at Banco de España, where he develops macro models to understand and forecast the economy. His research includes Adaptive Learning in DSGE models, forecast based on textual analysis and the design of climate change models. He holds a PhD in Economics from the Université Catholique de Louvain and a PhD in Quantitative Finance and Economics from the University of the Basque Country. Pablo has published in the *European Economic Review*, *Macroeconomic Dynamics* or *Economic Letters* among other journals.

Beatriz González is Research Economist at Banco de España (DG Economics, Statistics and Research). Her research focuses on the impact of firm heterogeneity and financial frictions on macroeconomic outcomes. She received her PhD in Economics from Universidad Carlos III de Madrid in 2019.

Samuel Hurtado is Head of the Macroeconomic Modelling unit at the Bank of Spain where he develops the in-house macro models for policy simulation and forecasting. His research includes heterogeneous-agents models, and the use of machine learning tools in economics. Samuel has several papers published in journals such as *IJCB*, *JEEA* and *Economic Modelling*, and one forthcoming in *Econometrica*.

SUERF Publications

Find more **SUERF Policy Briefs** and **Policy Notes** at www.suerf.org/policynotes

SUERF is a network association of central bankers and regulators, academics, and practitioners in the financial sector. The focus of the association is on the analysis, discussion and understanding of financial markets and institutions, the monetary economy, the conduct of regulation, supervision and monetary policy.

SUERF's events and publications provide a unique European network for the analysis and discussion of these and related issues.

SUERF Policy Briefs (SPBs) serve to promote SUERF Members' economic views and research findings as well as economic policy-oriented analyses. They address topical issues and propose solutions to current economic and financial challenges. SPBs serve to increase the international visibility of SUERF Members' analyses and research.

The views expressed are those of the author(s) and not necessarily those of the institution(s) the author(s) is/are affiliated with.
