Analytical work for the Fed's Framework Review

- No formal review of our modeling approaches
- Reliance on research expertise across the Federal Reserve System
- Series of 13 memos presented to the FOMC (publicly available)
 - Eclectic use of models: "standard" FRB/US, integrated balance sheet model, HANK, small-scale NK models, ...
- Memo #5: Hebden et al. (2020)
 - Robustness of the performance of makeup strategies to expectation formation
 - Three modelling exercises

Modeling exercise #1

- Makeup strategies like average inflation targeting (AIT) are superior to inflation targeting in theory
 - Expectation channel is crucial: promise of future higher inflation offsets low inflation today
 - strategy and its economic implications need to be understood by the public
- What if only parts of the public, e.g. financial markets, understand AIT?
- The FRB/US model consists of several blocks: asset pricing, price/wage setting, consumption, ...
- We can separately model expectations in these blocks
- Result: Chart
 - AIT is effective as long as financial markets understand its implications...
 - ...as spending in FRB/US responds to long-term borrowing rates

イロト 不得 とくほ とくほう

Modeling exercise #2

- A commitment to overshoot the inflation target could lead to an increase in long-run inflation expectations
- How do unanchored long-run inflation expectations affect AIT?
- The FRB/US Phillips curve allows for time-varying expected trend inflation (Cogley and Sbordone, 2008)
 - Long-run inflation expectations are a moving average of past inflation
- Result: Chart
 - Rising inflation expectations necessitate faster tightening...
 - ...and increase the costs of pursuing AIT.

< ロト (同) (三) (三)

Bodenstein et al. (2019)

- Spin-off of modeling exercise #3
- Existing literature on the evaluation of makeup strategies
 - either assume perfectly rational expectations
 - or permanent cognitive/behavioral frictions
- Agents may eventually understand the new strategy, but need to learn it from observing policy actions
- What happens in the transition?

イロト イポト イヨト イヨ

The Learning Model

- The economy is a system of equations (here: small NK model)
- The central bank follows a policy rule subject to a lower bound

$$i_{t} = \max \{i_{t}^{*}, \underline{i}\}$$

$$i_{t}^{*} = \rho_{i}i_{t-1} + (1 - \rho_{i})\left(\pi_{t} + \phi_{\pi t}\pi_{t} + \phi_{pt}\frac{p_{t}}{4} + \phi_{y}\frac{y_{t}^{gap}}{4}\right) + e_{t}$$

$$p_{t} = p_{t-1} + \pi_{t}$$

- Consider a switch from inflation targeting($\phi_{pt} = 0$) to PLT ($\phi_{\pi t} = 0$)
- Agents observe the policy rate, but not the rule parameters or policy shocks
 - Policymakers can't talk the talk, they've got to walk the walk
- Simultaneously solve for the non-linear Bayesian filtering problem and the equilibrium
 - non-linearity #1: ELB constraint
 - non-linearity #2: loss of information at the ELB

Transition to PLT leads to higher volatility due to learning

Starting PLT in a recession: no benefits, all costs

ъ

The ZLB makes it hard to learn about a new policy strategy

With learning, PLT cannot contain an inflation surge
